

WM7 - Computational and Systems Biology

A Mini UNIX Tutorial

Dietmar Rieder

What's UNIX?

- ◆ An operating system run on many servers/workstations
- ◆ Invented by [AT&T](#) Bell Labs in late 60's
- ◆ Currently there are different versions and variants of UNIX such as SunOS, Linux, Solaris, BSD, ...

Basic UNIX

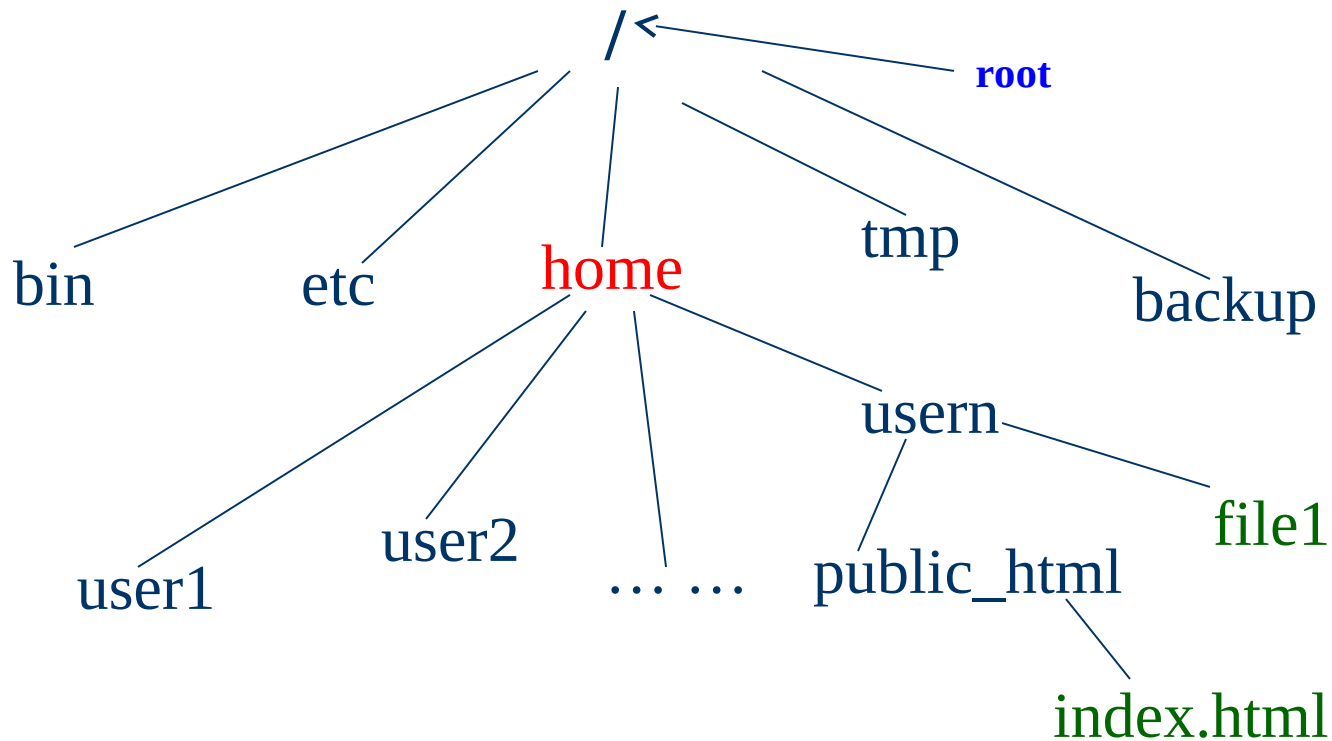

- ◆ Most UNIX functionality is accessed through the UNIX prompt.
 - Text based, like MS-DOS
- ◆ Mastery of UNIX comes from being familiar with different commands
 - We will cover some of the basic commands in this class
 - Goal: to be able to navigate through the directories

UNIX Directory Structure

- ◆ Files are grouped in the directory structure. The file-system is arranged like hierarchical tree structure.
- ◆ The top of the tree is called “root” which usually contains several sub-directories.
 - “/”(forward slash) is used to present the “root”.

What is Directory?

Directories can hold files and other directories

Pathnames

- ◆ Absolute Pathnames

- In the previous tree

`/home/usern/file1`

is an absolute pathname

- ◆ Relative pathnames

- If you are already in the `home` directory, the relative pathname for `file1` is

`usern/file1`

More on UNIX paths

- ◆ “~” (tilda) points to the user’s home directory. Useful if you are logging into a workstation with many users.
 - ◆ Many of the other paths are inaccessible and unimportant to you
 - ◆ ~ is the default working directory when you log in.
 - ◆ If you are user “usern”, then `/home/usern/file1` is the same as `~/file1`.
- ◆ “.” refers to the current directory
- ◆ “..” refers to the parent directory.
 - ◆ If you are in `/home/usern/`, then `../` refers to `/home/`.

UNIX – Basic commands

- ◆ **pwd** print process working dir
- ◆ **cat, head, tail...** view files
- ◆ **ls** list contents of directory
- ◆ **rm** remove file
- ◆ **mv** rename file
- ◆ **cp** copy a file
- ◆ **touch** create an empty file or update
- ◆ **mkdir** and **rmdir** create and remove dir
- ◆ **wc** counts the words in a file
- ◆ **du** directory usage

UNIX – More commands

Creation

- ◆ `mkdir` – make directory. Use “`mkdir name`” to create a new directory in the current directory named *name*. Can also create multiple directories.
- ◆ `cp` – copy. Use “`cp file1 file2`” to create a new file, *file2* which is a copy of *file1*. Can also use “`cp file(s) directory`” to copy all *file(s)* to *directory*.
- ◆ `mv` – move. Same as copy, but deletes the original file.

UNIX – More commands

Deletion – Be careful with these!

- ◆ rm – remove. Use “rm *file(s)*” to delete files
- ◆ rmdir – remove directory. Use it to delete an empty directory
- ◆ You can not recover your files after you removed them!

Some tips

- ◆ “tab” is used for auto-complete.
 - If a file/directory name was partly typed in, tab will auto-complete it.
 - If there are multiple options, tab will auto-complete up to the point where the options branch and show you a list of possible options
- ◆ “*” is used as a wild card.
 - “rm *blah**” removes all files which start with *blah*, so *blah1*, *blah2*, and *blahblah* would all be removed
 - Using “cp public/* private/” copies all files in your public directory into your private directory, and keeps all file names intact.
- ◆ Use arrow keys to navigate through the command history (up/down)

More tips

- ◆ “-r” is a common option that usually makes a command *recursive*, that is, it will execute the same command on all subdirectories.
 - Commonly used to perform file commands on directories
 - Using “cp private/* public/ -r” copies everything from the private folder to the public folder, and also copies all subdirectories.
 - Using “rm -r *” deletes everything in the current directory and all sub-directories. Never use this in the root directory!

Redirection of input/output

- ◆ Redirection of output: `>`
 - example: `$ ls > my_files`
- ◆ Redirection of input: `<`
 - example: `$ program <input.data`
- ◆ Append output: `>>`
 - example: `$ date >> logfile`
- ◆ Bourne Shell derivatives: `fd>`
 - example: `$ ls 2> error_log`

Connect to remote system

- ◆ We use SecureShell (ssh) to connect to a remote Linux server

icbi-courses.i-med.ac.at

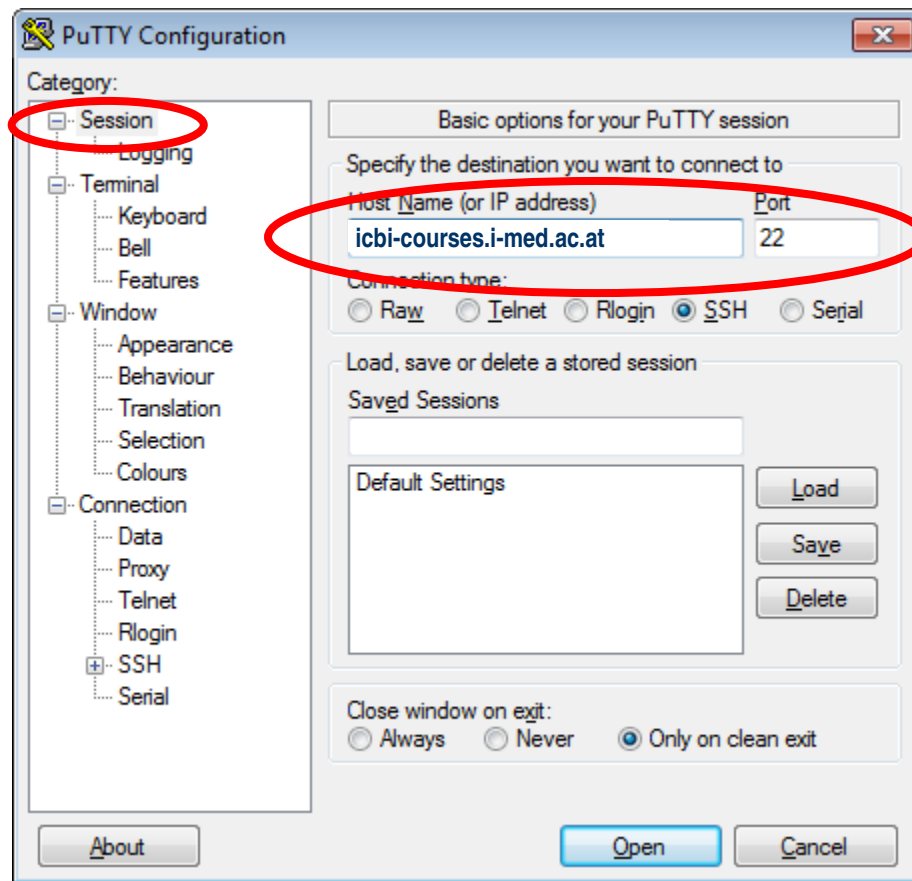

- ◆ ssh for Windows is provided by

putty

(<http://www.putty.org/>)

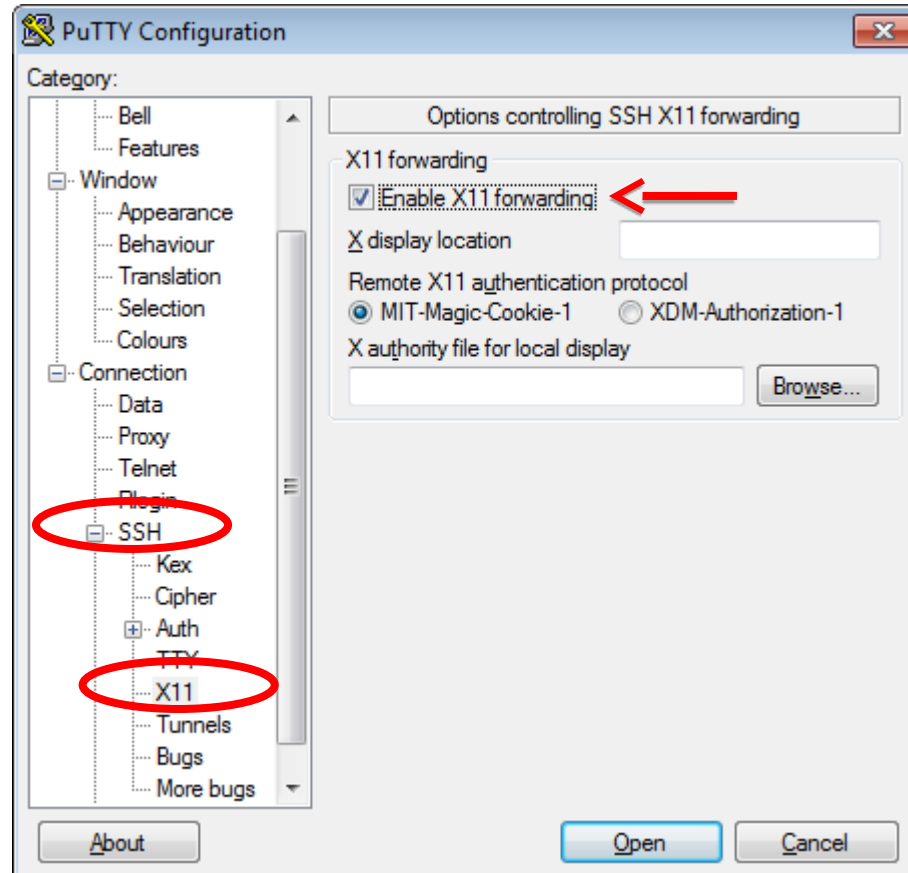

Connect to remote system

Define connection by specifying a remote host name

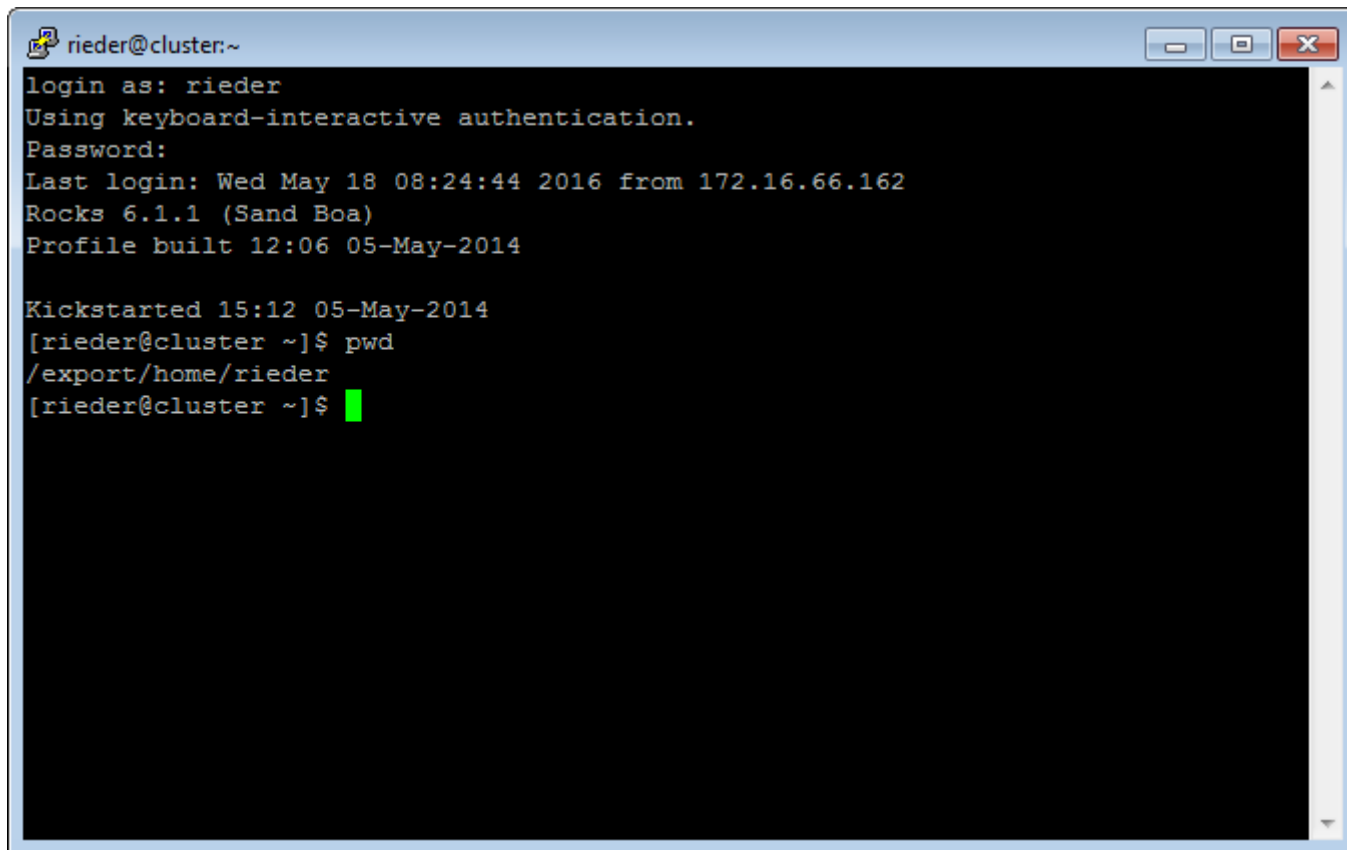

Connect to remote system

Enable X11 forwarding (redirection of graphical output) and start “Xming”

Connect to remote system

Welcome on cluster: enjoy working

```
rieder@cluster:~  
login as: rieder  
Using keyboard-interactive authentication.  
Password:  
Last login: Wed May 18 08:24:44 2016 from 172.16.66.162
